

Cooperative Programming

Discussion 03

Readings

This discussion pulls from three different required readings but is focused on Google Engineering Practices and Documentation. The ideas of pair programming and version control are introduced in the first two readings but come up again in the third in the context of version control. Pay special attention to the last learning outcome – you will likely be doing code reviews in your own team later this year!

Required

- 1) Software Engineering, Section 3.2.4 – Pair Programming (2 pages)
- 2) [Pro Git](#), Section 1.1 – About Version Control (4 pages)
- 3) [Google Engineering Practices Documentation](#) (39 pages)

Recommended

The first two readings are very light introductions to pair programming and version control, but there is much more to be said on both topics! I don't expect you to have much difficulty finding interesting Connections for both of these. Keep your focus off of the technical details of version control for now and think more about why it is worth investing your time into learning it. We will dive into the details later in the course.

Learning Outcomes

- Contrast at least two potential benefits and costs of pair programming
- Defend the use of version control for cooperative programming against potential arguments that it may be too confusing to use or learn to be worth the time
- Compare and contrast the responsibilities of the code reviewer and change author in the code review process described in Google Engineering Practices Documentation
- Decide on 4-5 principles from the Google Engineering Practices Documentation to prioritize to form a simplified code review guide for a fictional team
